

## Potato (*Solanum tuberosum L.*)

French: Pommes de terre; Spanish: Patatas; Italian: Patatas; German: Kartoffeln

### Crop data

Annual, but some crops in some areas overwintered in the ground prior to harvesting.

Planted (tubers) spring to early summer; in some areas doublecropped in one season by planting very early in spring, harvesting early - before full maturity - then again planting in summer.

Planting from true potato seeds (TPS) occurs in parts of Africa, Asia and South America. TPS can be sown directly into the field (although this has not developed beyond the experimental stage) or sown to produce plants for transplanting into the field (a technique which appears to be less favoured currently) or grown under controlled conditions to produce high numbers of small tubers per unit area (minitubers) which are then grown on in the field in a relatively traditional manner.

Flowers: some cultivars rarely, if ever, produce full flowers; others produce flowers but sterile seed; whereas yet others produce flowers, fruits (commonly called berries) and viable seed.

Initiation of "daughter" tubers occurs 5-12 weeks after planting of "mother" tubers, presuming these latter to have reached the end of their normal dormancy at planting and depending upon the extent to which the mother tuber has been physiologically aged.

Plant density: 30 000-100 000 tubers/ha dependant on cultivar ("normal" range in temperate conditions 30 000 - 60 000 tubers/ha). Within this range, planting density is varied according to the final market requirement in tuber size, the availability of moisture (especially irrigation) and, in some countries, the relative cost of seed tubers and ware (consumption) tubers.

Potatoes will grow on most soils but, where mechanical harvesting is operated, then lighter and medium bodied soils cause less difficulty in harvesting when weather conditions are adverse. Potatoes are grown on organic as well as mineral soils. Soil pH requirement: minimum 5.5 but below about pH 4.8 growth is impaired. Alkaline conditions can adversely affect skin quality and highly alkaline conditions can induce micronutrient deficiencies.

Continuous cropping with potatoes only occurs in a few special situations and therefore it is normally necessary to strike a compromise in pH requirement between the needs of potatoes and other rotational crops. In most mineral soil situations a compromise recommendation for pH is 6.0-7.0. It is imprudent to apply lime immediately before a potato crop except in cases of extreme acidity.

The crop responds well to moisture; irrigation is commonplace where it is grown on any scale. Irrigation at tuber initiation can affect the skin quality of daughter tubers by influencing phytopathogens, either favourably or adversely according to conditions, and amount of moisture present.

### Nutrient uptake/removal

## Fertilizer recommendations

Available organic manures are normally applied before seedbed preparation and ploughed or cultivated into the soil before planting. Frequently the nutritive value of such organic manures is unknown, and generally the amounts used are not recorded. It has been suggested that organic manures would enhance the water-holding capacity of the soil. However, pot experiments reported by Harris (1960) indicated such effects to be small, whilst Holliday et al.(1965) demonstrated yield benefits of up to 14 % from use of FYM in dry seasons. Experiments carried out by ADAS in England during the 1970s and 1980s have indicated that organic manures can have detrimental effects upon dry matter content (specific gravity) of potatoes for processing.

## Timing of application of fertilizers

N: Potatoes use large amounts of N, frequently more than the total applied as fertilizer (Anderson & Hewgill, 1978). Normally all N is applied to the seedbed at planting but in cases

where leaching by rainfall is likely (e.g. on sandy soils) there are often benefits from applying half in the seedbed and half at tuber initiation. On heavier soils in temperate areas the benefits from splitting N application are less predictable.

P: generally best applied in spring.

K: Where large amounts (e.g. > 400 kg/ha K<sub>2</sub>O) are to be applied, they are probably better split. Theory would suggest several months between the two applications, the last at or about planting, but agricultural field practice suggests that 6-8 weeks between dressings in temperate conditions is adequate. On all except the lightest or most K-deficient soils, there appears to be no disadvantage in autumn application of K fertilizer followed by spring potato planting.

Micronutrients: deficiencies are usually most efficiently corrected by foliar application.

## Preferred nutrient forms

N: usually as readily soluble materials.

P: generally as materials containing a high proportion of water-soluble phosphate applied at or immediately prior to planting.

K: application as sulphate rather than chloride provides some small benefits in the form of relative increases in tuber dry matter (specific gravity) and is most appropriate to potatoes for processing. The chloride, however, through its effects on reducing tuber dry matter, has beneficial effects in reducing tuber bruising at harvest, other factors being unchanged. Large dressings of KCl at planting will have a deteriorious effect on crop emergence in dry soils.

Mg: can be applied as a foliar spray where deficiency symptoms occur in the absence of extenuating circumstances (e.g. drought); more normally it would be applied in a Mg-containing fertilizer or, as a routine on inherently Mg-deficient soils, in Mg-containing lime.

## Fertilizer placement

Placement in close proximity but not in contact with seed tubers will produce more efficient fertilizer use. The risks of damage to tubers increase in dry conditions, on light soils, where pre-sprouted seed is planted, or where more than 250 kg/ha N plus K<sub>2</sub>O are applied together.

## Present fertilizer practices

### The Netherlands

Seed potatoes: fertilizer use depends upon cultivar and harvest date; the later a seed crop is harvested, the less N is applied.

Ware potatos:

N fertilizer requirement is calculated from the formula:

$$\text{N requirement} = 285 - (1.1 \text{ mineral N J/F}^*) \text{ (kg/ha)}$$

\* J/F - January/February

Mineral N is assessed in soil during January/February of the harvest year (= Mineral N J/F) and generally amounts to approximately 40 kg/ha N.

P and K requirements are calculated from soil status for these nutrients; whilst new soils high in Ca are given extra P.

Extra K is occasionally given to control bruising, presumably by its effect on dry matter.

| Netherlands - Recommended nutrient rates |         |         |         |
|--|---------|---------|---------|
| Crop use                                 | kg/ha   |         |         |
|  | N       | P2O5    | K2O     |
| Seed potatoes                            | 90-130  | 120-180 | ca. 200 |
| Potatoes for human consumption           | ca. 240 | 120-180 | 250-400 |
| Industrial potatoes                      | ca. 240 | 120-180 | 100-200 |

## France

| France - Recommended nutrient rates |         |         |         |
|-------------------------------------|---------|---------|---------|
| Maturity group                      | kg/ha   |         |         |
|                                     | N       | P2O5    | K2O     |
| Early varieties                     | 100-120 | 60-100  | 100-220 |
| Second early varieties              | 80-100  | 60-100  | 100-200 |
| Maincrop varieties                  | 60- 80  | 60-100  | 100-200 |
| New potatoes                        | 120-150 | 100-150 | 200-250 |
| Storage potatoes                    | 150-200 | 80-110  | 300-400 |
| Industrial potatoes                 | 150-200 | 80-120  | 250-300 |

Boron is used in deficient soils at no more than 15-20 kg/ha because of its potential toxicity.

## Germany: Former GDR

Nutrient supply to potatoes in organic manures and mineral fertilizers should match the crop requirement, which for P2O5 and K2O, is calculated from potential yield and soil nutrient status. A 30 t/ha crop would require 25 kg/ha P2O5 and 200 kg/ha K2O.

The N fertilizer recommendations which are set out below are for supplies from both mineral and organic sources for potatoes after a cereal crop (without overhead irrigation).

| Germany (former GDR) - Recommended nitrogen rates |           |         |         |           |
|---|-----------|---------|---------|-----------|
| Intended use                                      | Soil type |         |         |           |
|   | Sand      | Loamy   | Sandy   | Loam/Clay |
|   | kg/ha N   |         |         |           |
| Ware potatoes for human consumption               | 130-170   | 130-170 | 130-170 | 120-160   |
| Seed potatoes                                     | 80-120    | 80-120  | 80-120  | 70-100    |
| Industrial potatoes for starch production         | 120-140   | 130-150 | 140-160 | 110-140   |

Where potatoes are intended for stock feed, an extra 20 kg/ha N is recommended. Where irrigation is used, a further 20 kg/ha N is advised.

N fertilizer dressings are sometimes split, especially on light sandy soils

## Germany: Original FRG

| Germany (original FRG) - Recommended nutrient rates* |                      |         |        |         |       |
|--|----------------------|---------|--------|---------|-------|
| Type of potatoes                                     | Expected yield(t/ha) | kg/ha   |        |         |       |
|  |                      | N       | P2O5   | K2O     | MgO   |
| Early potatoes                                       | 15-20                | 100-140 | 70- 80 | 180-240 | 50-60 |
|  | 20-30                | 140-200 | 80-100 | 240-330 | 50-60 |
| Maincrop potatoes                                    | 25-30                | 100-120 | 70- 80 | 250-275 | 50-60 |
|  | 30-40                | 120-160 | 80-100 | 275-330 | 50-60 |

\* For sites with good nutrient supply (Class C)

## Italy

| Italy - Recommended nutrient rates |         |         |         |
|------------------------------------|---------|---------|---------|
| Type of potatoes                   | kg/ha   |         |         |
|                                    | N       | P2O5    | K2O     |
| Early harvested potatoes           | 150-200 | 100-150 | 150-200 |
| Human consumption potatoes         | 150-180 | 150-180 | 150-200 |
| Industrial potatoes                | 120-150 | 150-180 | 100-150 |
| Seed potatoes                      | 100-120 | 120-160 | 100-150 |

Where FYM is used rates of mineral fertilizers are reduced proportionally.

## UK: England & Wales

Recommendations are given according to maturity on harvest date, soil nutrient status index for each nutrient, and soil type. N rates relate to previous cropping (index 0 is normal after cereals) and use of organic manures, whilst P2O5, K2O and Mg rates are based on soil analysis.

| England & Wales - Recommended nutrient rates  |            |       |      |     |     |  |
|---|------------|-------|------|-----|-----|--|
| Variety   | Soil index | kg/ha |      |     |     |  |
|   |            | N     | P2O5 | K2O | MgO |  |
| Early and<br>canning potatoes   | 0          | 180a  | 350b | 180 | 170 |  |
|   | 1          | 130   | 300b | 150 | 80  |  |
|   | 2          | 80    | 250b | 120 | -   |  |

| a For every early lifts, 150 kg/ha N is adequate  |            |       |      |     |     |  |
| b Early potatoes have shown much larger response on slightly acid soils in Dyfed and Cornwall than on calcareous soils in S.E. England. The latter have shown little response to P at soil P Index 4, and 125 kg/ha P2O5 is sufficient. |            |       |      |     |     |  |

Potatoes for processing: crops grown for 'French fry' production should receive the same fertilizer treatment as if grown for the ware market.

The variety Record grown for crisping should not receive more N than is recommended for ware.

Choice of source and rate of K will depend on whether higher dry matter or reduced internal bruising is the priority. High rates of animal manure can result in excessive nutrient application and reduced crisp quality.

## UK: Scotland

Similar recommendations as for England & Wales, except as below:

## Finland

N requirements are taken from basic standards. Basic requirements for P2O5, K2O and Mg are calculated from soil analysis.

For all nutrients corrections are made for:

- effect of preceding crop
- organic manures
- irrigation/moisture stress
- method of fertilizer distribution, e.g. placement or broadcast

Computer programs are used to produce final individual recommendations.

For Long Island Mineral Soil apply Mg and at least 90 kg/ha each of N and P2O5 and all or part of K2O in bands at planting. If need is indicated by soil test, supplemental P2O5 and K2O can be applied between planting and emergence. The remainder of the N should be applied as a sidedressing when plants are 10-15 cm high.

For Upstate Mineral Soil, the entire application can be banded at planting, or at least 90 kg/ha N and all P2O5 and K2O can be applied at planting, with the remaining N applied as a sidedressing when the plants are 10-15 cm high.

In both locations, supplemental N applications may be needed if heavy rains occur early in the season, but they should not be made after plants are 20-25 cm high.

For Shallow Mucks, band all N at planting unless foliar applications of manganese sulphate are to be made; P2O5 and K2O can be broadcast or banded with N. For Deep Mucks, band or broadcast the required amount of fertilizer.

#### USA: Idaho

**N recommendations** vary from 22 to 337 kg/ha N based on the calculation:

$$\text{Requirement} = \frac{\text{Crop need} - (\text{mineralized N} + \text{soil test N})}{0.65 \text{ (% recovery fertilizer N)}}$$

| Idaho - P2O5 recommendations |                 |                 |  |
|------------------------------|-----------------|-----------------|--|
| Soil test P 0 - 30 cm ppm    | kg/ha P2O5      |                 |  |
|                              | < 5 % free lime | >15 % free lime |  |
| 5                            | 180             | 450             |  |
| 10                           | 90              | 360             |  |
| 20                           | 0               | 180             |  |
| 30                           | 0               | 0               |  |

| Idaho - K2O recommendations |           |
|-----------------------------|-----------|
| Soil test K 0-30 cm ppm     | kg/ha K2O |
| 0                           | 270       |
| 55                          | 180       |
| 100                         | 90        |
| >158                        | 0         |

Some N is applied in irrigation water. P2O5 and K2O can be applied in the autumn before planting of the spring potato crop.

Recommendations are not specifically given for sulphur but, where the level of S04-S in the 0-30 cm soil depth is less than 8 ppm, then treatment is advised in the form of water-soluble sulphate.

## Canada

General recommendations for the Atlantic regions are:

| kg/ha   |         |         |
|---------|---------|---------|
| N       | P2O5    | K2O     |
| 110-150 | 120-180 | 120-180 |

Mg fertilization is rarely required.

| <b>P2O5 recommendations</b> |                            |                   |
|-----------------------------|----------------------------|-------------------|
| <b>Yield potential t/ha</b> | <b>P2O5 status in soil</b> | <b>kg/ha P2O5</b> |
| 10                          | a                          | 30-100            |
| 20                          | b                          | 40-115            |
| 30                          | c                          | 50-130            |
| 40                          | d                          | 60-145            |
| 50                          | e                          | 70-160            |

a = ambic 0-4; Bray 1 0-5; Olsen 0-3 ppm P2O5  
e = ambic 20+; Bray 1 25+; Olsen 15 ppm P2O5

Required K is calculated from cation exchange capacity and soil analysis. Mg and Ca are applied as dolomitic or calcitic limestone.

## Other countries
